|  | Q6  | Explain the significance of back emf in DC motors.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|  | Ans | <ul style="list-style-type: none"> <li>• Counter-Electromotive Force: When a DC motor operates, it generates a voltage known as back EMF. This voltage is induced in the armature windings due to the motor's rotation. It opposes the applied voltage (the supply voltage) and is referred to as a counter-electromotive force because it counteracts the flow of current into the motor.</li> <li>• Armature Current Control: Back EMF affects the amount of current flowing through the armature (the rotating part of the motor). Ohm's law states that current (I) is directly proportional to voltage (V) and inversely proportional to resistance (R) in a circuit (<math>I = V / R</math>). The back EMF, which opposes the supply voltage, reduces the effective voltage across the armature. As a result, it limits the armature current and helps prevent excessive current flow, which could otherwise damage the motor. This self-regulating property is especially important during startup or when the motor is subjected to sudden load changes.</li> <li>• Speed Regulation: Back EMF is directly proportional to the motor's speed. As the motor spins faster, the back EMF increases. This relationship is described by the equation: <math>E_b = k\omega</math>, where <math>E_b</math> is the back EMF, k is a constant, and <math>\omega</math> is the angular velocity (speed) of the motor. By measuring the back EMF, you can indirectly determine the motor's speed. This property is valuable for maintaining precise control over the motor's speed in various applications.</li> </ul> |
|  | Q7  | Define voltage regulation. What is the reason for negative voltage regulation in transformers?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|  | Ans | <ul style="list-style-type: none"> <li>• When a transformer is loaded with a constant primary voltage, the secondary voltage decreases with increase in load.</li> <li>• This is because of its resistance and leakage reactance.</li> <li>• <b>The representation of the change in secondary terminal voltage from no-load to full-load as a percentage of full-load secondary terminal voltage is called Voltage Regulation.</b></li> <li>• Lesser this value, better the transformer, because a good transformer should keep its secondary voltage as constant as possible under all load conditions.</li> </ul> $\%regulation = \frac{V_{2\_NL} - V_2}{V_2}$ $\%regulation = \frac{I_1 r_{01} \cos \phi \pm I_1 x_{01} \sin \phi}{V_1} \times 100$ <p style="text-align: right;">+ : Lagging pf load<br/>- : Leading pf load</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Q9  |  | Explain the principle of on-load tap changing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Ans |  | <p>On-load tap changing (OLTC) is a mechanism used in transformers to adjust the turns ratio and thereby regulate the output voltage while the transformer is under electrical load. Its principle can be summarized in three key points:</p> <ul style="list-style-type: none"> <li>Continuous Voltage Regulation: The main principle of OLTC is to allow</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

*Answer any one full question from each module. Each question carries 14 marks*

### Module 1

- Q11 a) Explain the terms (i) winding pitch (ii) front pitch and (iii) back pitch related to DC armature windings. Discuss how these values are selected in lap and wave windings. (6 Marks)
- b) A 4 pole machine is wound with 564 conductors. The flux and speed are such that the average emf generated in each conductor is 2 V. The current in each conductor is 100A. Calculate the total current and the emf generated in the armature if the winding is (i) lap connected and (ii) wave connected. (8 Marks)

- Ans a)
- **Back pitch ( $Y_b$ ):** Distance between two coil sides of the same coil.
  - **Front pitch ( $Y_f$ ):** Distance between 2 coil sides connected to the same commutator segments.
  - **Winding pitch or Resultant pitch ( $Y_w$ ):** Distance between similar coil sides of consecutive coils.

#### Design of Double Layer Simplex Lap Winding

Back Pitch,  $Y_b = \frac{Z}{P} \pm K$  (where K is an integer or fraction to make back pitch an odd integer)

Winding Pitch,  $Y_w = \pm 2$  Z : Number of Conductor  
P : Number of Poles

Front Pitch,  $Y_f = Y_b - Y_w$

+ : for Progressive winding  
- : for Retrogressive winding

#### Design of Double Layer Wave Winding

Winding Pitch,  $Y_w = \frac{Z \pm 2}{P/2}$

$Y_w = Y_b + Y_f$  ( $Y_b$  and  $Y_f$  should be odd)

Z : Number of Conductor  
P : Number of Poles  
+ : for Progressive winding  
- : for Retrogressive winding

b) Given

| $21 + 7 = 28 = 4$ | $28 - 5 = 23$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                 |                  |             |             |              |              |              |              |              |              |              |               |               |               |               |               |               |               |               |               |                   |               |                   |               |                   |             |
| $23 + 7 = 30 = 6$ | $6 - 5 = 1$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                 |                  |             |             |              |              |              |              |              |              |              |               |               |               |               |               |               |               |               |               |                   |               |                   |               |                   |             |

## Module 2

- Q13 a) What are the effects of armature reaction on the operation of dc machine? What are the remedial measures taken to counter the effects of armature reaction? (8 Marks)
- b) Explain with neat sketches, the process of commutation in DC machines. (6 Marks)

Ans a) The action or effect of armature flux on main flux is known as armature reaction. There are mainly two effects:  
**Demagnetising effect:** It is the effect of armature flux that weakens the main flux.  
**Cross magnetising effect:** It is the effect of armature flux that distorts the main flux.

Since the resultant direction of the flux in the armature is shifted, the magnetic neutral axis (MNA) get shifted from GNA.

For sparkles commutation process, brushes should be placed along MNA. Now the MNA is shifted, positions of brushes also should be changed.

After changing brush positions, armature flux distribution also will be changed.

- Now  $\phi_a$  can be resolved in to 2 rectangular components  $\phi_c$  and  $\phi_d$
- Component  $\phi_d$  is in direct opposition to the main mmf. So it has a demagnetising effect on main flux and it is called **demagnetising (weakening) component of**

**armature reaction.**

- The component  $\phi_c$  is perpendicular to the main mmf. So it distort the main flux. Hence it is called **cross-magnetising (distorting) component of armature reaction.**
- The demagnetising effect leads to reduced generated voltage while cross-magnetising effect leads to sparking at the brushes.

**Methods to overcome armature reaction:**

- ❖ *To overcome demagnetizing effect, number of field windings should be increased so that the strength of main flux can be increased.*
- ❖ *To overcome cross magnetizing effect compensating windings need to be provided.*
- Compensating windings: Compensating windings are the auxiliary windings embedded in slots in the pole faces. They are connected in series with armature in a manner so that the direction of current through compensating conductors in any one pole face will be opposite to the current through the adjacent armature conductors.

- b) Whenever armature conductors are alternately comes under different poles, direction of current changes. But in external circuit, we get unidirectional current. The process of converting bidirectional current in the armature conductors to unidirectional current in the external circuit by means of commutator segments and brushes is called **Commutation process.**

In other words, the reversal of current in the armature coil by means of commutator segments and brushes is known as **Commutation.**

Fig. 4.24. Pertaining to the illustration of commutation process.

Figure (a)

- Brush is fully on commutator segment 1.
- Segment 1 conducts a current of  $2I_c$  to the brush.
- $I_c$  from coil A and  $I_c$  from the adjacent coil.

Figure (b)

- As armature rotates, brush makes contact with segment 2 and thus short circuits coil A.
- The brush is one-fourth on segment 2 and three-fourth on segment 1.
- Brush conducts a current of  $2I_c$ ;  $i$  through segment 2 and  $(2I_c - i)$  through segment 1.

Current in coil A is reduced to  $(I_c - i)$  from  $I_c$ .

Figure (c)

- The brush is one-half on segment 1 and one-half on segment 2.
- Brush conducts a current of  $2I_c$ ;  $I_c$  through segment 1 and  $I_c$  through segment 2.
- Current in coil A is reduced zero.

Figure (d)

- The brush is one-fourth on segment 1 and three-fourth on segment 2.
- Brush conducts a current of  $2I_c$ ;  $i$  through segment 1 and  $(2I_c - i)$  through segment 2.
- Coil A carries a current of  $(I_c - i)$  in the opposite direction.

Figure (e)

- The brush is fully on segment 2.
- Brush conducts a current of  $2I_c$ ;  $I_c$  through coil A and  $I_c$  from adjacent coil.
- Coil A carries a current of  $I_c$  but in the reverse direction.
- Thus coil A has undergone commutation.
- Each coil will undergo commutation in this way as it passes the brush axis.

- Q14 a) In a long-shunt compound generator, the terminal voltage is 230 V when the generator delivers 150 A. Determine (i) induced e.m.f. (ii) total power generated and (iii) power delivered to load. The shunt field, series field and armature resistance are

|     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

- When the voltmeter reads zero, switch can be closed.

#### b) Speed Control Techniques

##### Armature Control

- Resistance of armature circuit is varied to control the speed
- As resistance increases, speed decreases and vice versa
- This method is used when speed control below base speed is required.
- A variable resistance is directly connected in series with the armature of dc motor.
- Speed is varied by wasting power in this external resistor.
- Since it is an inefficient method of speed control, this method is not commonly used.

##### Field Control

- Flux is varied to control the speed
- Flux and speed are inversely proportional
- As flux increases, speed decreases and vice versa
- Since field flux is inversely proportional to the speed of motor, by varying field flux we can control the speed of motor.
- By decreasing the flux we can increase the motor speed and by increasing the flux we can decrease the speed.
- But, increasing of field flux is not preferred. It is because of the saturation of the magnetic core.
- So, by means of field flux control, speed of the motor is controlled only above base speed.

- Q16 a) A 200-V DC shunt motor takes 4A at no-load when running at 700 rpm. The field resistance is 100 Ω. The resistance of armature at standstill gives a drop of 6 volts across armature terminals when 10 A were passed through it. Calculate (a) speed on rated load

(b) torque developed in N-m with rated load applied and (c) efficiency. The rated input to the motor is 8 kW. (10 Marks)

b) Derive the torque equation of a DC motor (4 Marks)

Ans

a)

$$I_{sh} = \frac{V}{R_{sh}} = \frac{200}{100} = 2A$$

$$R_a = \frac{6}{10} = 0.6 \Omega$$

①. Case 1 - No load condition.

$$I_{L1} = 4A$$

$$N_1 = 700 \text{ rpm}$$

$$I_{a1} = I_{L1} - I_{sh} = 4 - 2 = 2A$$

$$\begin{aligned} E_{b1} &= V - I_{a1} R_a \\ &= 200 - (2 \times 0.6) \\ &= 198.8V \end{aligned}$$

Case 2 - rated condition

$$P_{in} = VI_L = 8 \text{ kW} = 8000 \text{ W}$$

$$I_{L2} = \frac{8000}{200} = 40A$$

$$I_{a2} = I_{L2} - I_{sh} = 40 - 2 = 38A$$

$$\begin{aligned} E_{b2} &= V - I_{a2} R_a = 200 - (38 \times 0.6) \\ &= 177.2V \end{aligned}$$

$$\frac{E_{b1}}{E_{b2}} = \frac{N_1}{N_2}$$

$$N_2 = N_1 \times \frac{E_{b2}}{E_{b1}} = 623.944 \text{ rpm}$$

$$\begin{aligned} \textcircled{b} \text{ Torque developed} &= \frac{\text{Power developed}}{\omega} \\ &= \frac{E_b I_a Z}{\frac{2\pi N_2}{60}} \\ &= \underline{\underline{103.06 \text{ Nm}}} \end{aligned}$$

$\textcircled{c}$  Here iron losses and mechanical losses are not given.  
so, only electrical efficiency can be calculated

$$\begin{aligned} \eta_{\text{ele.}} &= \frac{E_b I_a Z}{V I_L} = \frac{177.2 \times 38}{200 \times 40} \\ &= \underline{\underline{84.17\%}} \end{aligned}$$

b)

Let,

- Z : Number of armature conductors
- B : Magnetic field strength in Wb/m<sup>2</sup>
- I : Current in armature conductor ( $I_a/A$ )
- $\Phi$  : Flux per pole in Wb
- P : Number of poles
- A : Number of parallel paths
- $r_a$  : Radius of armature core
- l : Length of armature conductor

Force experienced on a single armature conductor,  $F = BIl \sin \theta = BIl$

Torque on each conductor,  $\tau = BIl \times r_a$

Torque experienced on armature,  $T = BIl r_a \times Z = Z \frac{\Phi I_a}{a A} l r_a$

Where 'a' is the cross-sectional area of flux path per pole and  $a = \frac{2\pi r_a l}{P}$

Therefore, Torque developed,  $T_e = \frac{Z \Phi I_a P}{2\pi A} = 0.159 Z \Phi I_a \frac{P}{A}$

#### Module 4

- Q17 a) With neat circuit diagram and relevant equations, explain how the efficiency of a transformer can be predetermined by conducting open circuit and short circuit tests. (10 Marks)

|     |    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|     |    | b) Derive emf equation of a transformer. (4 Marks)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Ans | a) | <p><b>Open Circuit (OC) Test</b></p> <ul style="list-style-type: none"> <li>▪ The purpose of this test is to determine the core losses and no-load current, which are helpful in finding <math>X_m</math> and <math>R_c</math>.</li> <li>▪ It is performed on the low voltage (LV) side of the transformer.</li> <li>▪ The other side (HV side) is left open.</li> <li>▪ A voltmeter, wattmeter and an ammeter are connected in the LV side as shown in figure.</li> <li>▪ Rated voltage is applied at the low voltage side.</li> <li>▪ Then meter readings are noted.</li> <li>▪ When rated voltage is applied at the LV side, rated flux is developed and thus core losses will occur.</li> <li>▪ Since the secondary side is open circuited, transformer will draw only the no-load current, and it will be very small. (2% – 5% of rated current).</li> <li>▪ Thus copper losses will be negligibly small at LV side and nil at HV side.</li> <li>▪ Hence, wattmeter reading indicates the core losses of the transformer.</li> <li>▪ Ammeter gives the no-load current.</li> </ul>  <p>Wattmeter reading, <math>W = V_1 I_e \cos \phi_o</math></p> $\cos \phi_o = \frac{W}{V_1 I_e} \Rightarrow \phi_o = \cos^{-1} \left( \frac{W}{V_1 I_e} \right)$ $I_m = I_e \sin \phi_o$ $I_c = I_e \cos \phi_o$ $X_m = \frac{V_1}{I_m}$ $R_c = \frac{V_1}{I_c}$ <p><b>Short Circuit (SC) Test</b></p> <ul style="list-style-type: none"> <li>▪ The purpose of this test is to determine the following: <ul style="list-style-type: none"> <li>→ Copper loss of the transformer at any load condition</li> <li>→ Voltage regulation</li> <li>→ Transformer impedance, leakage reactance and resistance.</li> </ul> </li> <li>▪ Low voltage side of the transformer is short circuited by a thick conductor.</li> <li>▪ A low voltage (5% - 10% of the rated value) is applied at the HV side and is gradually increased till full load currents are flowing through the windings.</li> <li>▪ Then meter readings are noted.</li> <li>▪ Applied voltage is only a small percentage of the rated value, flux developed will be</li> </ul> |

small and hence core losses can be neglected.

- Thus, wattmeter gives the full-load copper losses of the transformer.

Wattmeter reading,  $W = I_1^2 r_{01}$

$$r_{01} = \frac{W}{I_1^2}$$

$$Z_{01} = \frac{V_{sc}}{I_1}$$

$$x_{01} = \sqrt{Z_{01}^2 - r_{01}^2}$$

**Efficiency = Output Power / Input Power = Output Power / (Output Power + Losses)**

Total losses are calculated from SC and OC tests.

b)

When a sinusoidal voltage of frequency 'f' is applied across the primary windings, it produces a sinusoidal flux of same frequency.

Let, the flux at any instant can be given by  $\phi = \phi_m \sin \omega t$

According to Faraday's Law,

$$\text{Induced EMF, } e = -N \frac{d\phi}{dt}$$

Thus, induced EMF in Primary winding

$$\begin{aligned} e_1 &= -N_1 \frac{d\phi}{dt} = -N_1 \frac{d(\phi_m \sin \omega t)}{dt} \\ &= -N_1 \phi_m \omega \cos \omega t \\ &= -N_1 \phi_m \omega \sin(90 - \omega t) \\ &= N_1 \phi_m 2\pi f \sin(\omega t - 90) \end{aligned}$$

|     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

(10 Marks)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                 | b) | Explain how the power transfer from primary to secondary of an autotransformer takes place partly by conduction and partly by induction. (4 Marks)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Ans             | a) | <p>Online tap changing (OLTC) is a mechanism used in transformers to adjust the turns ratio and thereby regulate the output voltage while the transformer is actively supplying power to a load. It ensures that the voltage supplied to the load remains within acceptable limits, compensating for variations in load conditions and voltage drops in the distribution system. Here's an explanation of the principle of online tap changing with a simplified sketch:</p> <p><b>Components and Operation:</b></p> <p><b>Transformer Windings:</b> A typical transformer has two windings, a primary winding and a secondary winding. The primary winding is connected to the high-voltage source (HV), while the secondary winding is connected to the load and delivers low-voltage power.</p> <p><b>Tap Changer:</b> Inside the transformer tank, there is a tap changer mechanism that includes a set of tap leads connected to different points along the primary winding. These tap leads can be physically adjusted to change the point at which the primary winding is connected to the secondary winding.</p> <p><b>Motor Drive:</b> The tap changer mechanism is controlled by a motor drive system, which can be operated manually or automatically based on a voltage control system. In an automatic system, sensors continuously monitor the output voltage, and when it deviates from the desired setpoint, the motor drive adjusts the tap position.</p> <p><b>Operation Steps:</b></p> <p><b>Initial Position:</b> The tap changer is initially set to a particular tap position, which determines the turns ratio of the transformer. The turns ratio affects the output voltage.</p> <p><b>Load Variations:</b> As the load on the transformer varies or when there are voltage fluctuations in the grid, the output voltage may deviate from the desired level.</p> <p><b>Voltage Monitoring:</b> Sensors continuously monitor the output voltage. If the voltage</p> |

goes above or below the desired range, it triggers a tap-changing action.

**Tap Adjustment:** The motor drive system adjusts the position of the tap changer. By moving the tap leads to a different position along the primary winding, the turns ratio is altered, and the output voltage is adjusted accordingly.

**Steady-State Operation:** Once the new tap position is set, the transformer continues to supply power to the load with the corrected output voltage. This process happens seamlessly and without interrupting the power supply, making it an online operation.

Online tap changing ensures that the output voltage remains stable and within acceptable limits, optimizing the performance of the transformer and ensuring a reliable power supply to the load even under varying conditions

- b) An autotransformer is a type of transformer that uses a single winding for both the primary and secondary coils, with a portion of the winding shared between them. Power transfer in an autotransformer occurs partly by conduction and partly by induction. Conduction involves the direct flow of electrical current through the common winding, while induction involves the electromagnetic coupling between the primary and secondary windings, which induces voltage and facilitates power transfer. This combination of conduction and induction allows for efficient voltage transformation in autotransformers while minimizing the size and weight compared to conventional transformers with separate primary and secondary windings.
- Conduction (Direct Current Path):

In an autotransformer, there is a portion of the winding that is common to both the primary and secondary sides. This shared portion is called the common winding or the series winding.

When an AC voltage is applied to the primary side of the autotransformer, current flows through the common winding because it is in series with both the primary and secondary coils.

The current in the common winding creates a magnetic field around it due to Ampere's law, similar to how it works in a regular transformer.

This magnetic field couples with the secondary winding, inducing a voltage in the
